

Limitations of linear models

Richard Erickson Instructor

Course overview

- Chapter 1: Review and limits of linear model and Poisson regressions
- Chapter 2: Logistic (Binomial) regression
- Chapter 3: Interpreting and plotting GLMs
- Chapter 4: Multiple regression with GLMs

Workhorse of data science

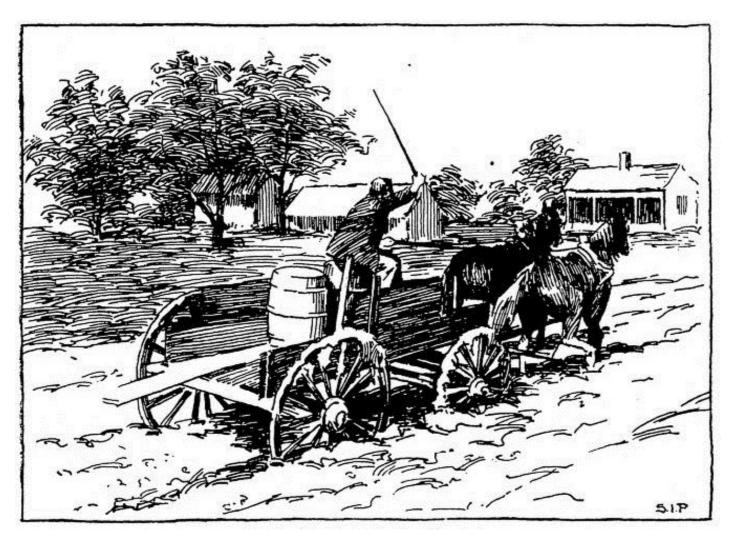

Image source: US Department of Agriculture

Linear models

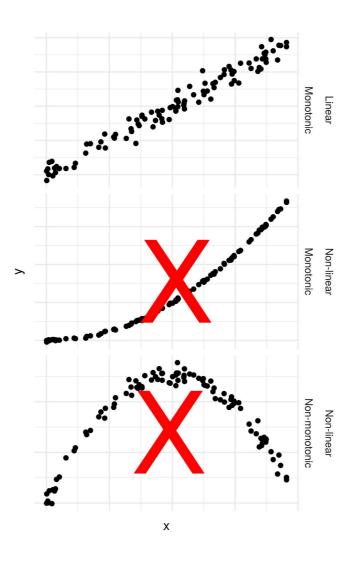

- How can linear coefficients explain the data?
- Intercept for baseline effect
- Slope for linear predictor
- $y = \beta_0 + \beta_1 x + \epsilon$

Linear models in R

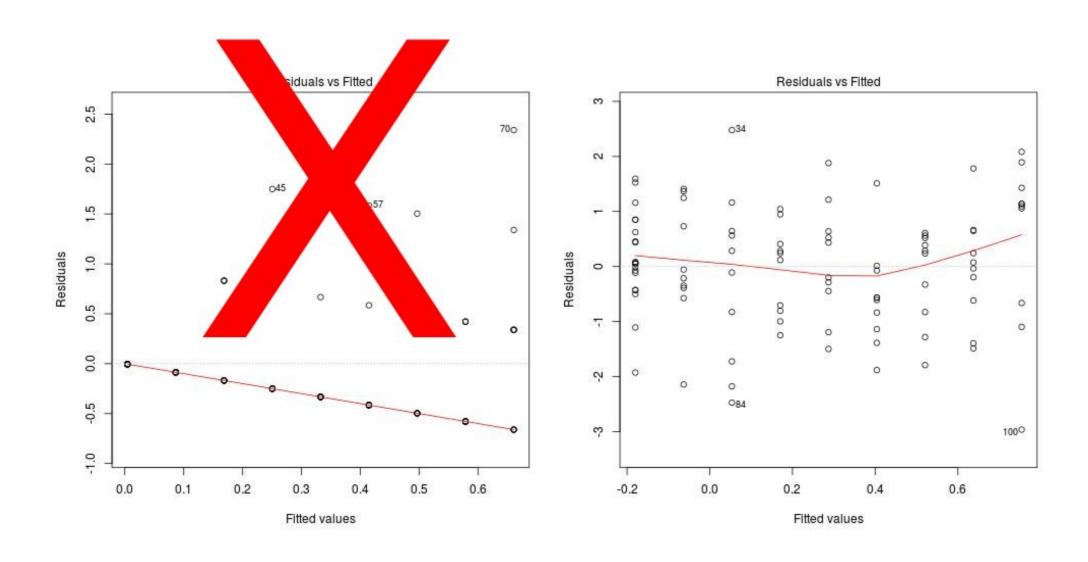

```
lm(y \sim x, data = dat)
```

Assumption of linearity

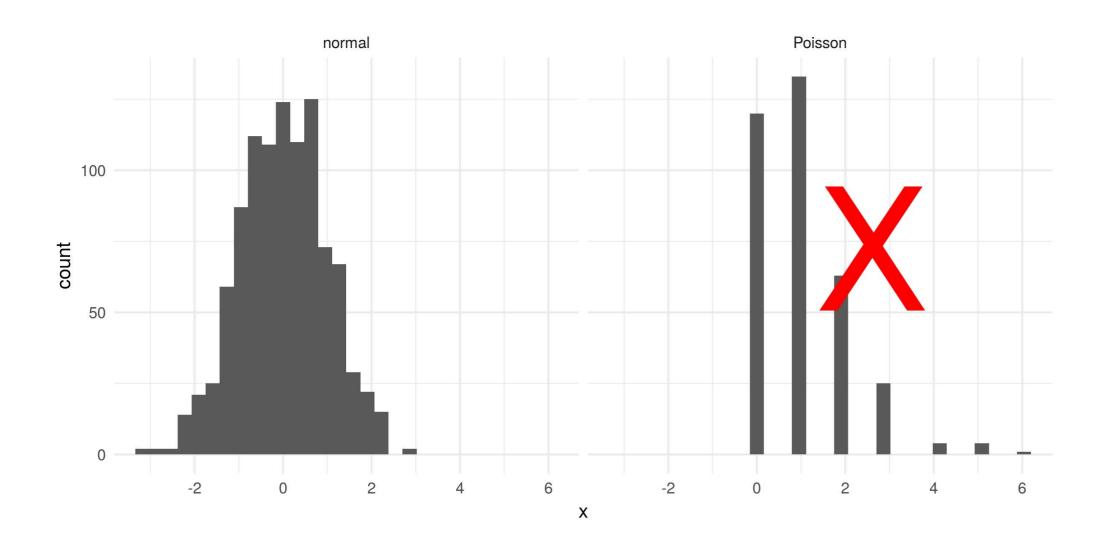

Assumption of normality

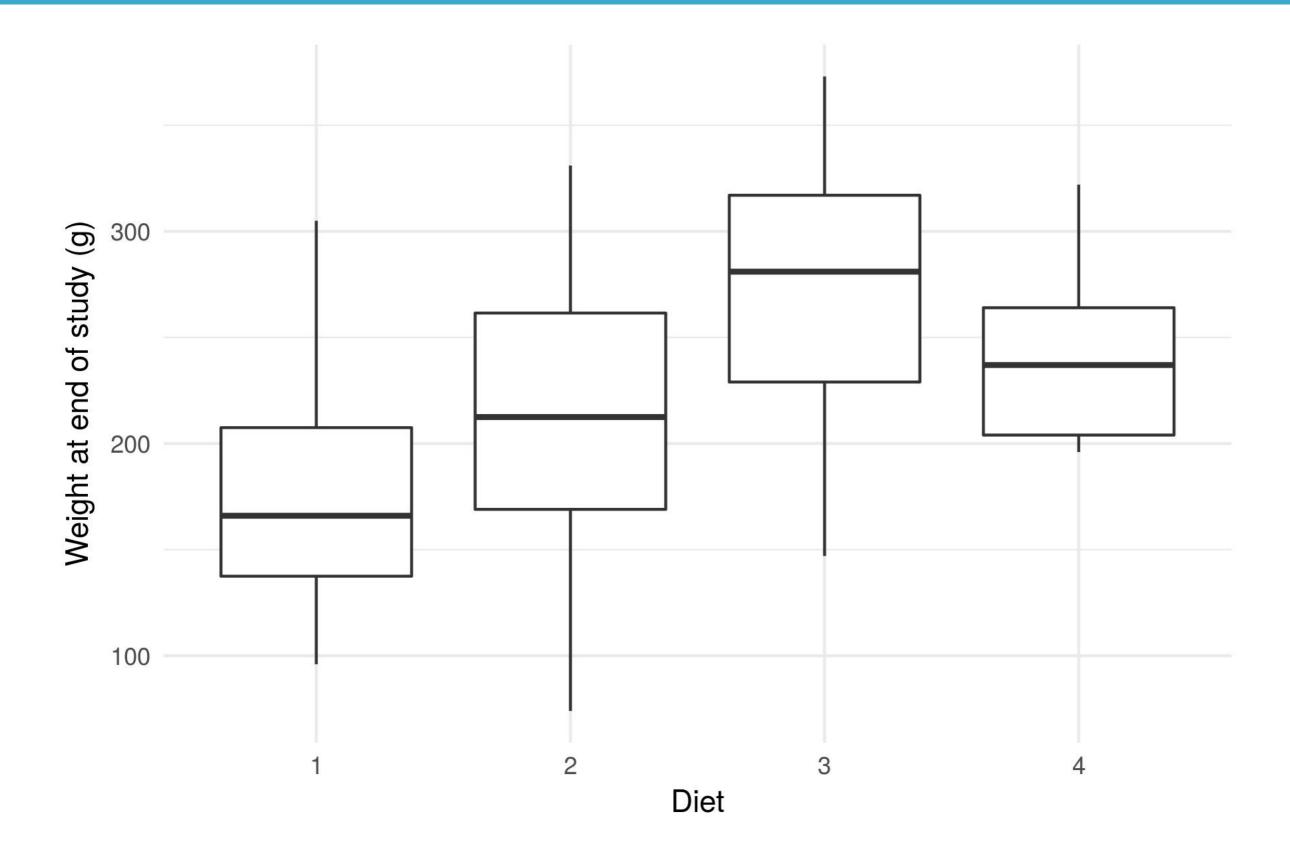

Assumption of continuous variables

Chick diets impact on weight

- ChickWeight data from datasets package
- ChickWeightsEnd last observation from study
- How do diets 2, 3, and 4 compare to diet 1?

What about survivorship or counts?

- What about chick survivorship or chick counts?
- Neither are continuous!
- We need a new tool
- The generalized linear model

Generalized linear model

- Similar to linear models
- Non-normal error distribution
- Link functions: $y = \psi(b_0 + b_1 x + \epsilon)$

GLMs in R

```
glm( y ~ x, data = data, family = "gaussian")
```

• lm() same as glm(..., family = "gaussian")

Let's practice!!

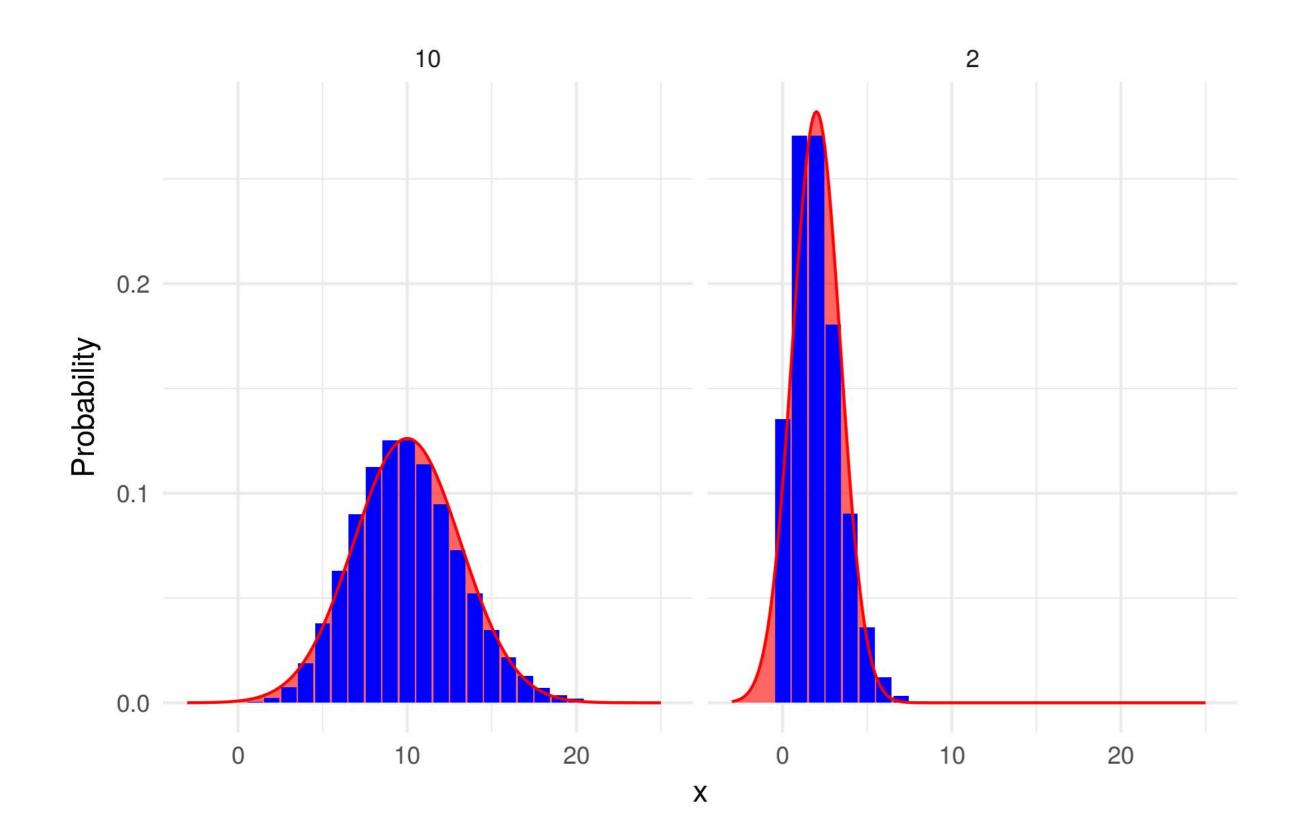

Poisson regression

Richard Erickson Instructor

Poisson distribution

- Discrete integers: x = 0, 1, 2, 3, ...
- Mean and variance parameter λ

$$ullet P(x) = rac{\lambda^x e^{-\lambda}}{x!}$$

• Fixed area/time (e.g., goal per one game)

Poisson distribution in R

```
dpois(x = \dots, lambda = \dots)
```

GLM with R requirements

- Discrete counts: 0, 1, 2, 3...
- Defined area and time
- Log-scale coefficients

GLM with Poisson in R

```
glm(y ~ x, data = dat, family = 'poisson')
```

When not to use Poisson distribution

- Non-count or non-positive data (e.g., 1.4 or -2)
- Non-constant sample area or time (e.g., trees km⁻¹ vs. trees m⁻¹)
- Mean ≥30
- Over-dispersed data
- Zero-inflated data

Formula intercepts

- Comparison or intercept
- Comparison formula = y ~ x
- Intercept formula = y ~ x 1

Goals per game

- Two players, which approach do we use?
- If we want to know difference between players, use comparison:

```
glm(goal ~ player, data = scores, family = "poisson")
```

• If we want to know average per player, use intercepts:

```
glm(goal ~ player -1, data = scores, family = "poisson")
```

Let's practice!

Basic Im() functions with glm()

Richard Erickson Instructor

Interacting with model objects

- Allow interaction with outputs
- Base R functions apply to glm()
- Useful shortcuts

Model print

• print() usually default

Model summary

• summary() provides more details

```
> summary(poissonOut)
# . . .
Deviance Residuals:
   Min 1Q Median 3Q Max
-1.6547 -0.9666 -0.7226 0.3830 2.3022
Coefficients:
           Estimate Std. Error z value Pr(>|z|)
(Intercept) -1.43036 0.59004 -2.424 0.0153 *
x 0.05815 0.02779 2.093 0.0364 *
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 '' 1
(Dispersion parameter for poisson family taken to be 1)
   Null deviance: 35.627 on 29 degrees of freedom
Residual deviance: 30.918 on 28 degrees of freedom
AIC: 66.024
Number of Fisher Scoring iterations: 5
```

Tidy output

- Tidyverse provides standardized model outputs
- tidy() from Broom package

Regression coefficients

• coef() prints regression coefficients

Confidence intervals

• confint() estimates the confidence intervals

```
> confint(poissonOut)
Waiting for profiling to be done...
2.5 % 97.5 %
(Intercept) -2.725545344 -0.3897748
x 0.005500767 0.1155564
```

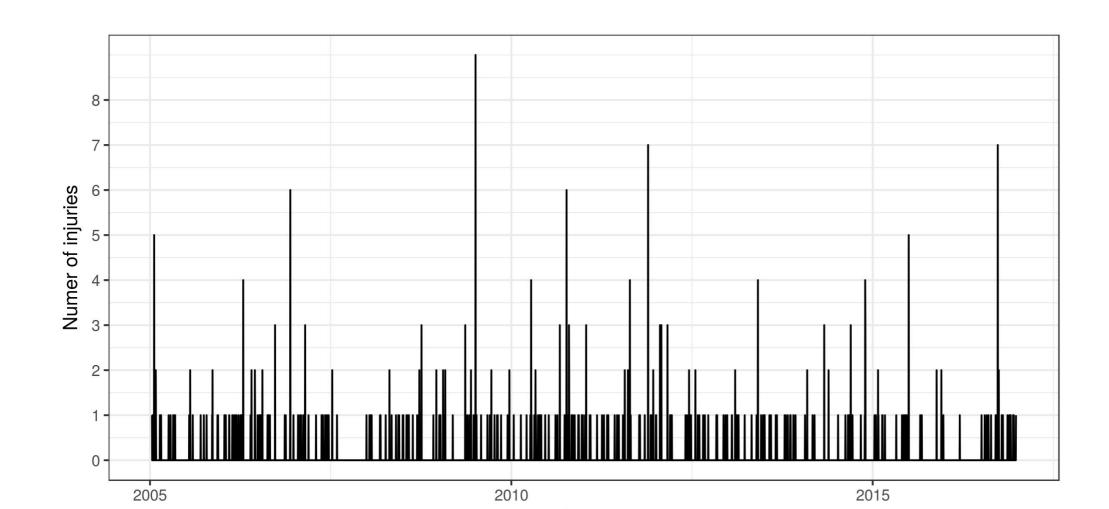

Predictions

- pred(model, newData)
- Structure of new data

Fire injury dataset

- Daily civilian injuries
- Louisville, KY
- Count data, many zeros

Let's practice!
